BPCIA Enrollment... IT'S HERE!

ГH

Sound Physicians

- For 20 years we have delivered exceptional results and outcomes to our hospital partners throughout the country.
- These results, coupled with a highly-engaged physician front line, have translated into success in value-based programs.
- 3,500+ employed clinicians
- 350+ hospital partners
- 40 states
- 80,000 BPCIA episodes per year not "cherry-picked"
- 1.5M+ annual hospital admissions

Sound Physicians Our BPCIA Experience: Learn, Invest, and Improve

Sound Aggregate Net Savings Rate

Sound Physicians **Engaged Hospitalists Drive Reduced Episode Costs**

\$3,000 \$2,425 \$2,500 \$2,350 \$2,075 \$2,000 \$2,000 \$2,000 \$1,900 \$1,825 \$1,625 \$1,425 \$1,500 \$1,400 \$1,325 \$1,050 \$1,000 \$725 \$575 \$500 **\$0** Q215 Q315 Q116 Q118 Q218 Q318 Q415 Q216 Q316 Q416 Q117 Q217 Q317 Q417

Savings per Episode

- Managing 80,000 episodes annually •
- Large clinical cross-section of • population
- *Effective 16% post-acute savings* • rate
- Compared to historical benchmarks:
 - 13% more patients sent home
 - 12% reduction in SNF LOS
 - 20% reduction in readmissions

Sound Physicians The Sound Secret Sauce

- Engaged physicians
- IT enable clinical workflows
- Strategic post-acute providers/networks
- Strong Analytics

Driving Success in BPCI-Advanced with Advanced Analytics

Today's Session

- BPCI-A methods and calculations primer
- Optimize bundle selection for maximum day one savings
 Optimize bundle is my target price?
 - How has my hospital changed since target price period?
 - Can I find more favorable pricing working with a PGP?
- Episode identification

BPCI-A Methods and Calculations Primer

BPCI Advanced

BPCI-A is a voluntary, nationwide model with a single retrospective bundled payment and one risk track, with a 90-day episode duration.

Confidential and Proprietary

- ACH, CCN and Hospital may be used interchangeably
- Physician group practice, provider group, PGP, and TIN may be used interchangeably
- <u>Bundle</u> refers unique clinical episode category and episode type combination
- Episode refers patient-level qualifying anchor stay and 90-day post-discharge period
- <u>Expected Episode Cost</u>: Patient episode-level prediction of total episode spend. If episode-level data
 were available for all patients, the average expected episode spend / the "dollar amount" would equal the
 ACH efficiency.
- <u>Favorability of Target Prices</u>: Comparison of HBP to best estimate of what the HBP would be if HBP had unlimited signal for each ACH-Bundle combination.
- <u>Time Zero Episode Spend</u>: Best estimate of current episode spend for each ACH-Bundle combination at start of program.
- <u>Clinical Improvement Opportunity</u>: Assessment of how much opportunity exists for each ACH -Bundle combination to lower spend beyond Time Zero estimate.
- <u>Selection Trigger</u>: Threshold at which ACH-Bundles are selected for inclusion in savings calculation. Triggers can be based on expected \$ or % improvement.

BPCI-A Financial Methodology Overview

Payment from CMS for BPCI Advanced involves:

- Standard Medicare FFS payments during episodes
- Retrospective reconciliation semi-annually during the program year
- Reconciliation compares all actual non-excluded Medicare FFS expenditures for a Clinical Episode to the final Target Price for that Clinical Episode
- Positive Reconciliation Amount, paid to Episode Initiators occurs when FFS payments for an episode are lower than the Target Price
- Negative Reconciliation Amount, paid by Episode Initiators occurs when FFS payments for an episode are higher than the Target Price
- Netting all Positive and Negative Reconciliation Amounts across all Clinical Episodes results in a Positive or Negative
 Total Reconciliation Amount
- In other words, NPRA = Target Price minus actual FFS expenditures
- For a full methodology description please see:

https://innovation.cms.gov/Files/fact-sheet/bpci-advanced-generalfs.pdf

Target Price Methodology

Target prices are set based on historical performance of episode initiator (hospital or provider group)

Small sample sizes on old episodes create significant opportunity for Bundle optimization

CMS Target Price Components

Hospital Level Calculations

- Step 7: Dollar Amount Average predicted spending for all baseline episodes across all ACHs for a given Bundle
- Step 8: ACH Efficiency Measure Hospital Observed/Expected ratio
- Step 9: SBS (standardized baseline spending) Dollar amount * ACH efficiency measure
- Step 10: PCMA Hospital Patient Case Mix Adjustment
- Step 11: PAT Factor Peer Adjusted Trend
- Step 12: HBP Hospital baseline price

PGP Adjustments

- Step 13: PGP efficiency measure PGP observed/expected ratio
- Step 14: PGP Offset PGP efficiency / Hospital efficiency
- Step 15: PGP Relative Case Mix PGP PCMA / Hospital PCMA
- Step 16: PGP-ACH Benchmark Price

Final Calculations

- Step 17: Preliminary Target Price (Benchmark Price * 0.97)
- Step 18: Ratio of real to standardized dollars for the hospital

CMS Statistical Methods

Replicated CMS calculation to obtain predicted clinical episode spending

- Used supplied documentation on 2 stage model Patient Case-mix Adjustment
- Compound lognormal (CL) & ordinary least square regression (OLS) Peer adjusted trend

https://downloads.cms.gov/files/cmmi/bpciadvanced-pricingmethodology-techreviewwebinar-slides.pdf https://innovation.cms.gov/Files/x/bpciadvanced-episodecreationspecs-yr1-2.pdf

Optimizing Risk/Episode Selection

Day 1 Savings Can Vary Widely

Data Sources for Analysis

- Applications included 326 distinct CCNs. This comprised 8,802 CCN, Episode type & Clinical episode category combinations
- Data included:
 - Target price details at both CCN & PGP level
 - Target price components
 - Episode details for Sound initiated episodes only
- Data were supplemented by CMS Limited Data Set (LDS) files (100% sample) to extend claims through 2018

Savings Opportunity Methodology Overview

TP Favorability	+/- what Target Price would have been had there been unlimited Sample
Efficiency Improvement	+/- how much efficiency has changed since target prices were set
PGP Price Advantage	+/- how much pricing advantage from PGP offset (if applicable)
Day 1 Savings	+/- how much pricing advantage from PGP offset (if applicable)

Questions to Consider

- 1. How favorable is my target price?
- 2. How has my hospital changed since target price period?
- 3. Can I find more favorable pricing working with a PGP?

Target Prices Have Significant Variability

Hospitals Have Predictable Utilization Patterns

Methodology – Target Price Favorability

Target Price Favorability =

(Hospital Baseline Price [HBP] * Signal)

+ (Predicted HBP * (1 – Signal))

Where as:

HBP is provided by CMS

Signal is derived through reliability adjustment based on Clinical Episode Category and sample size

Predicted HBP is result of modeling exercise

More Methodology – Target Price Favorability

Predicted HBP is a weighted average of:

- Actual efficiency measure in the clinical episode category (O/E from target price file)
- Proxy measure in the clinical episode category (model based on patient factors and postdischarge utilization)
- Actual efficiency measure from all other clinical episode categories
- Proxy measure from all other clinical episode categories

The weights depend on:

- Signal covariance and variance
- Patient-level error variance in each measure
- Sample sizes for each measure

Years Have Passed Since Target Prices Were Set

Methodology – Efficiency Improvement

 Reliability-adjusted hospital episode trend. Based on proxy models both within bundle and from related bundles, best estimate in change in spend from target price period to day one. This trend is multiplied by the reliability adjusted HBP to estimate Time Zero spend.

PGP Pricing Can Be Very Different

Confidential and Proprietary

Predicting Day 1 Savings – Example Hospital

What is My Opportunity to Improve?

Assessing performance on key utilization metrics and cost measures is key to understanding whether a bundle offers sufficient opportunity to improve relative to target prices.

Episode Identification

BPCI-A Identification Challenge

- The data which identifies a stay as definitively at-risk in BPCI-A aren't available until the episode is over.
- Episode management requires predicting eligibility

Arbor Bundle Eligibility Modeling Approach Multiple, hierarchical regression models

- 1. DRG Model uses HL7 Diagnosis Codes
 - HL7 Diagnostic Codes are used to predict DRG probabilities (Diagnostic Regression Model)
 - DRG predictions are filtered by TIN/Bundle eligibility based on Sound participation
 - ADIME + Subsequent Stay probabilities are used to predict Bundle Eligibility (Bundle Eligibility Regression Model)
 - Real-time data are supplemented with CMS unreconciled claims
- 2. Bundle Eligibility Model uses ADIMES probabilities [0-100]
 - Attending Physician probability
 - Diagnostic (DRG) eligible BPCIA Episode at TIN
 - Inpatient Stay
 - Medicare Eligible Stay
 - Exclusions to BPCIA for stay/patient
 - Subsequent stay to ongoing episode (Readmission)

You Can Predict BPCI-A Eligibility in Real-time
